

REMARKS

The present application was filed on October 12, 2001 with claims 1 through 27. Claims 11-24 and 27 were withdrawn from consideration due to a restriction requirement. Consequently, claims 1-10, 25, and 26 are pending.

5 In the Office Action, the Examiner rejected claims 1-10, 25, and 26 under (i) 35 U.S.C. §112, first paragraph, as failing to comply with the written description requirement; (ii) 35 U.S.C. §112, second paragraph, as being indefinite for failing to particularly point out and distinctly claim the subject matter which applicant regards as the invention; and (iii) 35 U.S.C. §112, second paragraph, as being incomplete for omitting essential steps, such omission
10 amounting to a gap between the steps. The Examiner also rejected claims 1, 2, 7, 8, 25, and 26 under 35 U.S.C. §102(e) as being anticipated by Noguchi (United States Patent Number 6,611,939 B1), rejected claims 3, 9, and 10 under 35 USC §103(a) as being unpatentable over Noguchi in view of Cameron (United States Patent Number 5,099,482 A), and rejected claim 4 under 35 USC §103(a) as being unpatentable over Noguchi and Cameron, in view of Oh et al.
15 (United States Patent Number 6,256,763 B1). The Examiner has indicated that claims 5 and 6 would be allowable if rewritten in independent form including all of the limitations of the base claims.

Section 112 Rejections

20 Regarding the written description requirement, the Examiner asserts that “nowhere in the specification does the Applicant teach ‘wherein said reduced power mode consumes less power in a given interval of time relative to a normal operating mode’ and in particular, the Applicant never mentions ‘operating mode’ much less ‘normal operating mode’ anywhere in the specification.”

25 Applicant notes that the present disclosure teaches that the reduced power mode consumes less power relative to a normal operating mode on, for example, page 2, lines 9-28, and page 13, line 13, to page 17, line 11. A person of ordinary skill in the art would recognize that power is measured per unit of time. For example, a “watt” is defined as “an International System unit of *power* equal to *one joule per second*.” (See, dictionary.com; emphasis added.) Thus, a person of ordinary skill in the art would understand that one mode can “consume less
30 power in a given interval of time” than another mode. Applicant also notes that, in the context of

the present invention, a person of ordinary skill in the art would recognize the meaning of the terms “operating mode” and “normal operating mode.” Thus, in light of the present specification, a person of ordinary skill in the art would understand the meaning of the phrase “wherein said reduced power mode consumes less power in a given interval of time relative to a
5 normal operating mode.”

Regarding the Examiner’s rejection of the cited claims as being indefinite for failing to particularly point out and distinctly claim the subject matter which applicant regards as the invention, the Examiner asserts that the term “relative to” is a relative term which renders the claims indefinite, and that the cited term is not defined by the claim, that the specification does
10 not provide a standard for ascertaining the requisite degree, and that one of ordinary skill in the art would not be reasonably apprised of the scope of the invention.

Contrary to the Examiner’s assertion, the cited claims *are definite* since they specifically recite the two modes (reduced power mode and normal operating mode) and recite how the reduced power mode compares to a normal operating mode, i.e., the reduced power
15 mode *consumes less power in a given interval of time* relative to (than) a normal operating mode.

Regarding the Examiner’s rejection of the cited claims as being incomplete for omitting essential steps, such omission amounting to a gap between the steps, the Examiner asserts that the omitted elements are: the relationship between “given interval of time” and “normal operating mode;” and the relationship between “reduced power mode” and “given
20 interval of time.”

Applicant notes that the relationships between operational modes (e.g., a normal operating mode and a reduced power mode) and an interval of time are inherent relationships, i.e., each mode inherently operates over an interval of time, and inherently consumes a certain amount of power per unit of time, as would be apparent to a person of ordinary skill in the art.

25 Independent Claims 1, 25 and 26

Independent claims 1, 25, and 26 were rejected under 35 U.S.C. §102(e) as being anticipated by Noguchi. In particular, the Examiner asserts that Noguchi teaches performing error correction in a reduced power mode...(the abstract in Noguchi teaches that error correction is terminated to reduce power consumption). In the Response to Arguments section of
30 the final Office Action dated August 18, 2005, the Examiner asserts that Noguchi teaches

“reducing the power consumption in the error correction processing means’ by reducing the number of iterations in the iterative decoding process means.”

Applicant notes that, as the Examiner acknowledges, Noguchi teaches that error correction is **terminated** to reduce power consumption (see, col. 3, lines 12-25; col. 5, lines 54-62; col. 9, lines 18-40 and 54-60). Noguchi teaches, for example, that,

further, the clock signal which is supplied to the data error correction device is stopped *during a period after the error correction processing is terminated* when the decoding has been repeated less than the predetermined number of times, till the iterative decoding for the next data is started. Therefore, the power consumption in the data error correction device can be further reduced. (Col. 9, lines 54-60; emphasis added.)

Noguchi teaches to **terminate** error correction and, as a result, reduces power consumption; the present disclosure teaches to **perform** error correction in a reduced power mode. The specific language of col. 9, lines 54-60, controls over the general language cited by the Examiner at col. 4, lines 61-67. Thus, a person of ordinary skill in the art would understand Noguchi as teaching to **terminate** error correction to reduce power consumption. The present disclosure teaches to **perform** error correction in a reduced power mode. Independent claims 1, 25, and 16 require that the reduced power mode *consumes less power in a given interval of time relative to a normal operating mode*. Support for this amendment can be found on page 2, lines 15-18; page 13, lines 13-17; page 14, lines 12-18; page 15, lines 23-27; and page 21, lines 17-30, of the originally filed specification.

Thus, Noguchi does not disclose or suggest wherein said reduced power mode consumes less power in a given interval of time relative to a normal operating mode, as required by independent claims 1, 25, and 26.

Additional Cited References

Cameron was also cited by the Examiner for its disclosure of the use of the particular elements of a decoder for Reed-Solomon codes and how an uncorrectable error is determined from intermediate polynomials. Applicant notes that Cameron is directed to determining whether a received message that has been Reed-Solomon encoded is correctable by Euclid’s algorithm. Cameron does not address the issue of performing error correction in a reduced power mode.

Thus, Cameron does not disclose or suggest wherein said reduced power mode consumes less power in a given interval of time relative to a normal operating mode, as required by independent claims 1, 25, and 26.

Oh et al. was also cited by the Examiner for its disclosure of the use of the modified Euclidean Algorithm. Applicant notes that Oh is directed to a Reed-Solomon decoder having a polynomial arrangement architecture for realizing a modified Euclidean algorithm and a decoding method. Oh et al. do not address the issue of performing error correction in a reduced power mode.

Thus, Oh et al. do not disclose or suggest wherein said reduced power mode consumes less power in a given interval of time relative to a normal operating mode, as required by independent claims 1, 25, and 26.

Claims 3, 4, 9 and 10

Claims 3, 4, 9, and 10 were rejected under 35 USC §103(a) as being unpatentable over Noguchi in view of Cameron. The Examiner acknowledges that Noguchi does not explicitly teach the specific use of the particular elements of a decoder for Reed-Solomon codes nor does Noguchi teach how an uncorrectable error is determined, but asserts that Cameron discloses that the test for uncorrectable errors comprises determining if the degree of the Error Locator Polynomial and the degree of the Error Magnitude Polynomial are less than predetermined values. In the Response to Arguments section of the present Office Action, the Examiner asserts that the Error Locator Polynomial and the degree of the Error Magnitude Polynomial are intermediate polynomials and uncorrectable errors are a result of exceeding the maximum error correction capability of a code.

Applicant notes that claim 3 requires providing a plurality of intermediate polynomials, and wherein the step of reducing power consumption in the error correction system when the actual number of errors is less than the maximum error correction capability further comprises the step of determining *if a degree of at least one of the intermediate polynomials is less than a predetermined degree* and claim 4 requires wherein one intermediate polynomial is a *first error evaluator polynomial* $R(x)$, wherein one intermediate polynomial is a *first error locator polynomial* $F(x)$, wherein $R^{(r+1)}(x) = F^{(r+1)}(x) \cdot S(x) \bmod x^{2t}$, wherein r is a number of

iterations, $S(x)$ is a syndrome polynomial, and t is a number of errors capable of being corrected, wherein one intermediate polynomial is a second error evaluator polynomial $Q(x)$, wherein one intermediate polynomial is a *second error locator polynomial* $G(x)$, wherein $Q^{(r+1)}(x) = G^{(r+1)}(x) \cdot S(x) \bmod x^{2t}$, wherein the step of determining if a degree of at least one of the intermediate polynomials is less than a predetermined degree further comprises the step of determining *if a degree of either $R(x)$ or $Q(x)$ is less than a predetermined degree, wherein $R(x)$ and $F(x)$ are valid when a degree of $R(x)$ is less than the predetermined degree, and wherein $Q(x)$ and $G(x)$ are valid when a degree of $Q(x)$ is less than the predetermined degree.* Claims 9 requires wherein the method further comprises the steps of *providing a key equation solving device in the decoder, and providing a plurality of syndrome generators, each of the syndrome generators determining one of the syndromes, wherein the key equation solving device is coupled to each of the syndrome generators, and wherein the step of reducing power consumption of the decoder of the error correction system when all syndromes have the predetermined value further comprises the step of not enabling the key equation solving device when all of the syndromes have the predetermined value* and claim 10 requires calculating at least one error polynomial when at least one syndrome does not have the predetermined value.

Applicant could find no disclosure or suggestion by Cameron of these limitations in the cited prior art. In particular, Cameron does **not** disclose or suggest determining *if a degree of at least one of the intermediate polynomials is less than a predetermined degree, does not* disclose or suggest wherein one intermediate polynomial is a *first error evaluator polynomial* $R(x)$, wherein one intermediate polynomial is a *first error locator polynomial* $F(x)$, wherein $R^{(r+1)}(x) = F^{(r+1)}(x) \cdot S(x) \bmod x^{2t}$, wherein r is a number of iterations, $S(x)$ is a syndrome polynomial, and t is a number of errors capable of being corrected, wherein one intermediate polynomial is a second error evaluator polynomial $Q(x)$, wherein one intermediate polynomial is a *second error locator polynomial* $G(x)$, wherein $Q^{(r+1)}(x) = G^{(r+1)}(x) \cdot S(x) \bmod x^{2t}$, wherein the step of determining if a degree of at least one of the intermediate polynomials is less than a predetermined degree further comprises the step of *determining if a degree of either $R(x)$ or $Q(x)$ is less than a predetermined degree, wherein $R(x)$ and $F(x)$ are valid when a degree of $R(x)$ is*

less than the predetermined degree, and wherein $Q(x)$ and $G(x)$ are valid when a degree of $Q(x)$ is less than the predetermined degree. Cameron also does **not** disclose or suggest providing a key equation solving device in the decoder, and providing a plurality of syndrome generators, each of the syndrome generators determining one of the syndromes, wherein the key equation solving device is coupled to each of the syndrome generators, and wherein the step of reducing power consumption of the decoder of the error correction system when all syndromes have the predetermined value further comprises the step of *not enabling the key equation solving device when all of the syndromes have the predetermined value* and does **not** disclose or suggest calculating at least one error polynomial when at least one syndrome does not have the predetermined value.

Thus, Noguchi and Cameron, alone or in combination, do not disclose or suggest providing a plurality of intermediate polynomials, and wherein the step of reducing power consumption in the error correction system when the actual number of errors is less than the maximum error correction capability further comprises the step of determining if a degree of at least one of the intermediate polynomials is less than a predetermined degree, as required by claim 3, do not disclose or suggest wherein one intermediate polynomial is a first error evaluator polynomial $R(x)$, wherein one intermediate polynomial is a first error locator polynomial $F(x)$, wherein $R^{(r+1)}(x) = F^{(r+1)}(x) \cdot S(x) \bmod x^{2t}$, wherein r is a number of iterations, $S(x)$ is a syndrome polynomial, and t is a number of errors capable of being corrected, wherein one intermediate polynomial is a second error evaluator polynomial $Q(x)$, wherein one intermediate polynomial is a second error locator polynomial $G(x)$, wherein $Q^{(r+1)}(x) = G^{(r+1)}(x) \cdot S(x) \bmod x^{2t}$, wherein the step of determining if a degree of at least one of the intermediate polynomials is less than a predetermined degree further comprises the step of determining if a degree of either $R(x)$ or $Q(x)$ is less than a predetermined degree, wherein $R(x)$ and $F(x)$ are valid when a degree of $R(x)$ is less than the predetermined degree, and wherein $Q(x)$ and $G(x)$ are valid when a degree of $Q(x)$ is less than the predetermined degree, as required by claim 4, do not disclose or suggest wherein the method further comprises the steps of providing a key equation solving device in the decoder, and providing a plurality of syndrome generators, each of the syndrome generators determining one of the syndromes, wherein the key equation

solving device is coupled to each of the syndrome generators, and wherein the step of reducing power consumption of the decoder of the error correction system when all syndromes have the predetermined value further comprises the step of not enabling the key equation solving device when all of the syndromes have the predetermined value, as required by claim 9, and do not
5 disclose or suggest calculating at least one error polynomial when at least one syndrome does not have the predetermined value, as required by claim 10.

Claim 7

Claim 7 was rejected under 35 U.S.C. §102(e) as being anticipated by Noguchi. In particular, the Examiner asserts that flagging the B1 decoding using the SYN(B1) flag is a
10 means for determining if all the syndromes have the predetermined value of zero or not, and that Noguchi teaches that whenever $SYN(B1)=0$ and $UNC(A1)=0$, correction is terminated thereby reducing power (FIG. 2). In the Response to Arguments section of the present Office Action, the Examiner asserts that SYN(B1) can only equal zero when all of the syndromes of the codeword B1 equal the predetermined value of zero.

15 Claims 7 requires determining a plurality of syndromes; determining if all of the syndromes have a predetermined value; and *reducing power consumption of the decoder of the error correction system when all of the syndromes have the predetermined value*. Applicant could find no disclosure or suggestion by Cameron of reducing power consumption of the decoder of the error correction system *when all of the syndromes have the predetermined value*.

20 Thus, Noguchi, Cameron, and Oh et al., alone or in combination, do not disclose or suggest determining a plurality of syndromes; determining if all of the syndromes have a predetermined value; and reducing power consumption of the decoder of the error correction system when all of the syndromes have the predetermined value, as required by claim 7.

Conclusion

25 The rejections of the cited claims under section 102 and 103 in view of Noguchi, Cameron, and Oh et al., alone or in any combination, are therefore believed to be improper and should be withdrawn. The remaining rejected dependent claims are believed allowable for at least the reasons identified above with respect to the independent claims. The Examiner has
30 already indicated that claims 5 and 6 would be allowable if rewritten in independent form

including all of the limitations of the base claims.

The Examiner's attention to this matter is appreciated.

Respectfully,

A handwritten signature in cursive script that reads "Kevin M. Mason".
